

PROBES :- (Health check)

PROBES :- used to determine the health and readiness of containers running within pods.

Probes are 3 types :-

- 1) Readiness probes :- are used to indicate when a container is ready to receive traffic
2. Liveness probes :- are used to determine whether a container is still running & responding to requests.
- 3, Startup Probes :- are used to determine whether the application within the container has started successfully.
It's used to delay the liveness and readiness probes until the application is ready to handle traffic.
